

Problem D. Jogo

Time Limit 2000 ms

Mem Limit 262144 kB

Leha somehow found an array consisting of n integers. Looking at it, he came up with a task. Two players play the game on the array. Players move one by one. The first player can choose for his move a subsegment of non-zero length with an odd sum of numbers and remove it from the array, after that the remaining parts are glued together into one array and the game continues. The second player can choose a subsegment of non-zero length with an even sum and remove it. Loses the one who can not make a move. Who will win if both play optimally?

Input

First line of input data contains single integer n ($1 \leq n \leq 10^6$) — length of the array.

Next line contains n integers $a_1, a_2, \dots, a_n$ ($0 \leq a_i \leq 10^9$).

Output

Output answer in single line. "First", if first player wins, and "Second" otherwise (without quotes).

Examples

Input	Output
4 1 3 2 3	First

Input	Output
2 2 2	Second

Note

In first sample first player remove whole array in one move and win.

In second sample first player can't make a move and lose.
